Description

SPHINGOSINE-1-PHOSPHATE LYASE POLYPEPTIDES,
POLYNUCLEOTIDES AND MODULATING AGENTS AND METHODS OF
5 USE THEREFOR

Technical Field

The present invention relates generally to cancer detection and
10 therapy. The invention is more particularly related to sphingosine-1-phosphate
lyase polynucleotides and polypeptides, and to agents that modulate the
expression and/or activity of such polypeptides. Such agents may be used, for
example, to diagnose and/or treat cancers such as breast cancer.

15 Background of the Invention

Breast cancer is a significant health problem for women in the
United States and throughout the world. Although advances have been made in
detection and treatment of the disease, breast cancer remains the most common
form of cancer, and the second leading cause of cancer death, in American
20 women. Among African-American women and women between 15 and 54 years
of age, breast cancer is the leading cause of cancer death. One out of every eight
women in the United States will develop breast cancer, a risk which has increased
52% during 1950-1990. In 1994, it is estimated that 182,000 new cases of female
breast cancer were diagnosed, and 46,000 women died from the disease.

25 No vaccine or other universally successful method for the
prevention or treatment of breast cancer is currently available. Management of
the disease currently relies on a combination of early diagnosis (through routine
breast screening procedures) and aggressive treatment, which may include one or
more of a variety of treatments such as surgery, radiotherapy, chemotherapy and
30 hormone therapy. The course of treatment for a particular breast cancer is often
selected based on a variety of prognostic parameters, including an analysis of

specific tumor markers. However, the use of established markers often leads to a result that is difficult to interpret.

With current therapies, tumor invasiveness and metastasis is a critical determinant in the outcome for breast cancer patients. Although the five
5 year survival for women diagnosed with localized breast cancer is about 90%, the five year survival drops to 18% for women whose disease has metastasized. Present therapies are inadequate for inhibiting tumor invasiveness for the large population of women with this severe disease.

Accordingly, improvements are needed in the treatment, diagnosis
10 and prevention of breast cancer. The present invention fulfills this need and further provides other related advantages.

Summary of the Invention

Briefly stated, the present invention provides compositions and
15 methods for the diagnosis and therapy of cancer. Within one aspect, the present invention provides isolated polynucleotides comprising a sequence selected from the group consisting of: (a) a sequence recited in SEQ ID NO:1; (b) a sequence recited in SEQ ID NO:3; (c) nucleotide sequences that hybridize to a polynucleotide complementary to either of the foregoing sequences under
20 moderately stringent conditions, wherein the nucleotide sequences encode polypeptides having sphingosine-1-phosphate lyase activity; and (d) nucleotide sequences that encode a polypeptide encoded by any of the foregoing sequences.

Within a related aspect, an isolated polynucleotide is provided that encodes a polypeptide recited in SEQ ID NO:2, or a variant of such a polypeptide
25 that has sphingosine-1-phosphate lyase activity. In another related aspect, an isolated polynucleotide comprising a sequence recited in SEQ ID NO:4, or a variant of such a polypeptide that has sphingosine-1-phosphate lyase activity, is provided.

Recombinant expression vectors comprising any of the foregoing
30 polynucleotides, and host cells transformed or transfected with such expression vectors, are also provided.

Within further aspects, SPL polypeptides are provided. Such polypeptides may be encoded by any of the foregoing polynucleotides. Alternatively, a polypeptide may comprise an amino acid sequence recited in SEQ ID NO:2 or 4, or a variant thereof, wherein the polypeptide has sphingosine-1-phosphate lyase activity.

Within a further aspect, the present invention provides isolated polynucleotides comprising at least 100 nucleotides complementary to a sequence recited in SEQ ID NO:1 or 3.

Within other aspects, methods are provided for preparing a sphingosine-1-phosphate lyase, comprising culturing a host cell transformed or transfected with a polynucleotide as described above under conditions promoting expression of the polynucleotide and recovering a sphingosine-1-phosphate lyase.

In further aspects, the present invention provides methods for identifying an agent that modulates sphingosine-1-phosphate lyase activity. In one such aspect, the method comprises: (a) contacting a candidate agent with cells that express sphingosine-1-phosphate lyase; and (b) subsequently measuring the level of sphingosine-1-phosphate lyase or mRNA encoding sphingosine-1-phosphate lyase in the cells, relative to a predetermined level in the absence of candidate agent. Within another such aspect, the method comprises: (a) contacting a candidate agent with a polypeptide comprising a sequence recited in any one of SEQ ID NOs: 2, 4, 6 or 8, or a variant of such a sequence having sphingosine-1-phosphate lyase activity, wherein the step of contacting is carried out under conditions and for a time sufficient to allow the candidate modulator to interact with the polypeptide; and (b) subsequently measuring the ability of the polypeptide to degrade sphingosine-1-phosphate or a derivative thereof, relative to an ability in the absence of candidate agent. The step of contacting may be performed by incubating a cell expressing the polypeptide with the candidate modulator, and the step of measuring the ability to degrade sphingosine-1-phosphate may be performed using an *in vitro* assay and a cellular extract.

The present invention further provides pharmaceutical compositions comprising an agent that modulates sphingosine-1-phosphate lyase

activity in combination with a pharmaceutically acceptable carrier. Such agents preferably inhibit sphingosine-1-phosphate lyase activity. Such inhibition may be achieved by inhibiting expression of an endogenous SPL gene, or by inhibiting the ability of an endogenous SPL to degrade sphingosine-1-phosphate. Within certain
5 preferred embodiments, a modulating agent comprises a polynucleotide or an antibody or an antigen-binding fragment thereof.

Within still further aspects, the present invention provides methods for modulating sphingosine-1-phosphate activity, comprising contacting a sphingosine-1-phosphate lyase with an effective amount of an agent that
10 modulates sphingosine-1-phosphate lyase activity, wherein the step of contacting is performed under conditions and for a time sufficient to allow the agent and the sphingosine-1-phosphate lyase to interact. To modulate sphingosine-1-phosphate lyase activity in a cell, a cell expressing sphingosine-1-phosphate may be contacted with such an agent.

15 Within related aspects, the present invention provides methods for inhibiting the growth of a cancer cell, comprising contacting a cancer cell with an agent that inhibits sphingosine-1-phosphate lyase activity. In a preferred embodiment, the cancer cell is a breast cancer cell.

The present invention also provides methods for inhibiting the
20 development and/or metastasis of a cancer in a mammal, comprising administering to a mammal an agent that inhibits sphingosine-1-phosphate lyase activity. Within certain embodiments, an agent may comprise, or be linked to, a targeting component, such as an anti-tumor antibody or a component that binds to an estrogen receptor.

25 Within other aspects, methods for diagnosing cancer in a mammal are provided, comprising detecting an alteration in an endogenous sphingosine-1-phosphate lyase gene in a sample obtained from a mammal, and therefrom diagnosing a cancer in the mammal. In certain embodiments the cancer is breast cancer and the sample is a breast tumor biopsy.

30 In related aspects, the present invention provides methods for evaluating a cancer prognosis, comprising determining the presence or absence of

an alteration in an endogenous sphingosine-1-phosphate lyase gene in a sample obtained from a mammal afflicted with cancer, and therefrom determining a prognosis.

The present invention further provides isolated antibodies that bind
5 to a polypeptide having a sequence recited in any one of SEQ ID NOs: 2, 4 or 6. Such antibodies may be polyclonal or monoclonal, and may inhibit the ability of a polypeptide having a sequence recited in any one of SEQ ID NOs: 2, 4 or 6 to degrade sphingosine-1-phosphate.

In still further aspects, the present invention provides methods for
10 detecting sphingosine-1-phosphate lyase in a sample, comprising: (a) contacting a sample with an antibody as described above under conditions and for a time sufficient to allow the antibody to bind to sphingosine-1-phosphate lyase; and (b) detecting in the sample the presence of sphingosine-1-phosphate lyase bound to the antibody.

Kits for use in the above methods are also provided. A kit for
15 detecting sphingosine-1-phosphate lyase in a sample comprises an antibody as described above and a buffer or detection reagent. A kit for detecting an alteration in a sphingosine-1-phosphate gene in a sample comprises a polynucleotide and a detection reagent.

20 Within further aspects, the present invention provides transgenic animals in which sphingosine-1-phosphate lyase activity is reduced, and cell lines derived from such transgenic animals.

These and other aspects of the present invention will become
apparent upon reference to the following detailed description and attached
25 drawings. All references disclosed herein are hereby incorporated by reference in their entirety as if each was incorporated individually.

Brief Description of the Drawings

Figures 1A-1C present the sequence of a *S. cerevisiae*
30 polynucleotide encoding a representative SPL polypeptide

Figures 2A and 2B present the sequence of a *C. elegans* polynucleotide encoding a representative SPL polypeptide.

Figures 3A and 3B present the sequence of a *Mus musculus* polynucleotide encoding a representative SPL polypeptide.

5 Figure 4 presents a comparison of the endogenous SPL genomic sequences from *C. elegans*, yeast and mouse.

Figure 5 is a photograph showing the growth of yeast cells grown to saturation in liquid culture and then plated on YPD with (top plate) and without (lower plate) 50μM sphingosine. On each plate, the top row of cells is BST1Δ
10 (JS16, which is a variation of SGP3 (*leu2-3,112 trp1 ura3-52 his3 ade8 rasI::HIS3*) in which the *BST1* gene has been replaced by a G418-resistant marker, *NEO*). The second row is JS16 transformed with vector alone. The third row and the bottom two rows (mBST1) show JS60 cells (JS16[pYES-mouseSPL]) and the fourth row (ceBST1) shows JS61 cells (JS16[pYES2-*C. elegans*BST1]).
15 The fifth row on each plate (BST1-WT) shows the growth of the wildtype SGP3 strain.

Figure 6A is an autoradiogram showing the products of an SPL assay performed on extracts obtained from JS16 transformed with JS29=pYES2-yeast *BST1* (ytBST1), JS60=pYES2-mouseSPL (mBST1) or pYES2 without
20 insert (vehicle control). Figure 6B is a histogram depicting the activity in the strains shown in Figure 6A, as determined by scraping a TLC plate as shown in Figure 6A and assessing the level of radioactivity.

Figure 7 is an autoradiogram depicting the results of a Northern blot analysis of the level of mouse SPL in various mouse tissues, as indicated.

25 Figures 8A-8C present a sequence of a human polynucleotide encoding a representative SPL polypeptide.

Detailed Description of the Invention

As noted above, the present invention is generally directed to
30 compositions and methods for the diagnosis and therapy of cancers such as breast cancer. The invention is more particularly related to sphingosine-1-phosphate

lyase (SPL) polypeptides, which have the ability to cleave sphingosine-1-phosphate into inactive metabolites, and to polynucleotides encoding such polypeptides. Sphingosine-1-phosphate is an endogenous tumor-suppressor lipid that potently inhibits breast cancer cell growth and invasiveness, while not affecting the growth of non-tumor cells (*see* Sadahira et al., *Proc. Natl. Acad. Sci. USA* 89:9686-90, 1992). *In vivo*, SPL catalyzes the cleavage of sphingosine-1-phosphate at the C₂₋₃ carbon bond to yield a long chain aldehyde and ethanolamine phosphate, the final step in the degradation of all higher order sphingolipids. Agents that decrease the expression or activity of endogenous SPL polypeptides are encompassed by the present invention. Such modulating agents may be identified using methods described herein and used, for example, in cancer therapy. It has also been found, within the context of the present invention, that the detection of alterations in an endogenous SPL sequence can be used to diagnose cancer, and to assess the prognosis for recovery. The present invention further provides such diagnostic methods and kits.

As used herein, the term "polypeptide" encompasses amino acid chains of any length, including full length endogenous (*i.e.*, native) SPL proteins and variants of endogenous sequences. "Variants" are polypeptides that differ in sequence from a native SPL only in substitutions, deletions and/or other modifications, such that the variant retains SPL activity, which may be determined using a representative method described herein. Within an SPL polypeptide variant, amino acid substitutions are preferably made at no more than 50% of the amino acid residues in the native polypeptide, and more preferably at no more than 25% of the amino acid residues. Such substitutions are preferably conservative. A conservative substitution is one in which an amino acid is substituted for another amino acid that has similar properties, such that one skilled in the art of peptide chemistry would expect the secondary structure and hydrophobic nature of the polypeptide to be substantially unchanged. In general, the following amino acids represent conservative changes: (1) ala, pro, gly, glu, asp, gln, asn, ser, thr; (2) cys, ser, tyr, thr; (3) val, ile, leu, met, ala, phe; (4) lys, arg, his; and (5) phe, tyr, trp, his. Substitutions, deletions and/or amino acid

additions may be made at any location(s) in the polypeptide, provided that the modification does not diminish the SPL activity of the variant. Thus, a variant may comprise only a portion of a native SPL sequence. In addition, or alternatively, variants may contain additional amino acid sequences (such as, for example, linkers, tags and/or ligands), preferably at the amino and/or carboxy termini. Such sequences may be used, for example, to facilitate purification, detection or cellular uptake of the polypeptide.

The SPL activity of an SPL polypeptide may generally be assessed using an *in vitro* assay that detects the degradation of labeled substrate (*i.e.*, sphingosine-1-phosphate, or a derivative thereof). Within such assays, pyridoxal 5'-phosphate is a requirement for SPL activity. In addition, the reaction generally proceeds optimally at pH 7.4-7.6 and requires chelators due to sensitivity toward heavy metal ions. The substrate should be a D-*erythro* isomer, but in derivatives of sphingosine-1-phosphate the type and chain length of sphingoid base may vary. In general, an assay as described by Van Veldhoven and Mannaerts, *J. Biol. Chem.* 266:12502-07, 1991 may be employed. Briefly, a solution (*e.g.*, a cellular extract) containing the polypeptide may be incubated with 40 μ M substrate at 37°C for 1 hour in the presence of, for example, 50 mM sucrose, 100 mM K-phosphate buffer pH 7.4, 25 mM NaF, 0.1% (w/v) Triton X-100, 0.5 mM EDTA, 2 mM DTT, 0.25 mM pyridoxal phosphate. Reactions may then be terminated and analyzed by thin-layer chromatography to detect the formation of labeled fatty aldehydes and further metabolites. In general, a polypeptide has SPL activity if, within such an assay: (1) the presence of 2 - 50 μ g polypeptide (or 0.1 - 10 mg/mL) results in a statistically significant increase in the level of substrate degradation, preferably a two-fold increase, relative to the level observed in the absence of polypeptide; and (2) the increase in the level of substrate degradation is pyridoxal 5'-phosphate dependent.

Within certain embodiments, an *in vitro* assay for SPL activity may be performed using cellular extracts prepared from cells that express the polypeptide of interest. Preferably, in the absence of a gene encoding an SPL polypeptide, such cells do not produce a significant amount of endogenous SPL

(i.e., a cellular extract should not contain a detectable increase in the level of SPL, as compared to buffer alone without extract). It has been found, within the context of the present invention, that yeast cells containing deletion of the SPL gene (*BST1*) are suitable for use in evaluating the SPL activity of a polypeptide.

5 *bst1*Δ cells can be generated from *S. cerevisiae* using standard techniques, such as PCR, as described herein. A polypeptide to be tested for SPL activity may then be expressed in *bst1*Δ cells, and the level of SPL activity in an extract containing the polypeptide may be compared to that of an extract prepared from cells that do not express the polypeptide. For such a test, a polypeptide is preferably expressed on

10 a high-copy yeast vector (such as pYES2, which is available from Invitrogen) yielding more than 20 copies of the gene per cell. In general, a polypeptide has SPL activity if, when expressed using such a vector in a *bst1*Δ cell, a cellular extract results in a two-fold increase in substrate degradation over the level observed for an extract prepared from cells not expressing the polypeptide.

15 A further test for SPL activity may be based upon functional complementation in the *bst1*Δ strain. It has been found, within the context of the present invention, that *bst1*Δ cells are highly sensitive to *D-erythro*-sphingosine. In particular, concentrations as low as 10 μM sphingosine completely inhibit the growth of *bst1*Δ cells. Such a level of sphingosine has no effect on the growth of

20 wildtype cells. A polypeptide having SPL activity as provided above significantly diminishes (i.e., by at least two fold) the sphingosine sensitivity when expressed on a high-copy yeast vector yielding more than 20 copies of the gene per cell.

In general, SPL polypeptides, and polynucleotides encoding such polypeptides, may be prepared using any of a variety of techniques that are well

25 known in the art. For example, a DNA sequence encoding native SPL may be prepared by amplification from a suitable cDNA or genomic library using, for example, polymerase chain reaction (PCR) or hybridization techniques. Libraries may generally be prepared and screened using methods well known to those of ordinary skill in the art, such as those described in Sambrook et al., *Molecular*

30 *Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratories, Cold Spring

Harbor, NY, 1989. cDNA libraries may be prepared from any of a variety of sources known to contain enzymes having SPL activity. SPL activity is ubiquitous with regard to species and mammalian tissues, with the exception of platelets, in which SPL activity is notably absent. In rat tissues, the highest levels of activity have been demonstrated in intestinal mucosa, liver and Harderian gland, with low activity in skeletal muscle and heart. Activity has also been demonstrated in a number of human (hepatoma cell line HB 8065, cervical carcinoma HeLa), mouse (hepatoma line BW1, mouse embryo 3T3-L1, Swiss 3T3 cells) and other cell lines, as well as in human cultured fibroblasts. Preferred cDNA libraries may prepared from human liver, intestine or brain tissues or cells. Other libraries that may be employed will be apparent to those of ordinary skill in the art. Primers for use in amplification may be readily designed based on the sequence of a native SPL polypeptide or polynucleotide, as provided herein.

Alternatively, an endogenous SPL gene may be identified using a screen for cDNAs that complement the *BST1* deletion in yeast. A cDNA expression library may be generated using a regulatable yeast expression vector (e.g., pYES, which is available from Invitrogen, Inc.) and standard techniques. A yeast *bst1* Δ strain may then be transformed with the cDNA library, and endogenous cDNAs having the ability to functionally complement the yeast lyase defect (i.e., restore the ability to grow in the presence of D-erythro-sphingosine) may be isolated.

An endogenous SPL gene may also be identified based on cross-reactivity of the protein product with anti-SPL antibodies, which may be prepared as described herein. Such screens may generally be performed using standard techniques (see Huynh et al., "Construction and Screening cDNA Libraries in λ gt11," in D.M. Glover, ed., *DNA Cloning: A Practical Approach*, 1:49-78, 1984 (IRL Press, Oxford)).

Polynucleotides encompassed by the present invention include DNA and RNA molecules that comprise an endogenous SPL gene sequence. Such polynucleotides include those that comprise a sequence recited in any one of SEQ ID NOs:1, 3, 5 and 7. Also encompassed are other polynucleotides that

5 encode an SPL amino acid sequence provided in any one of SEQ ID NOs: 2, 4, 6 and 8, as well as polynucleotides that encode variants of a native SPL sequence that retain SPL activity. Polynucleotides that are substantially homologous to a sequence complementary to an endogenous SPL gene are also within the scope of the present invention. "Substantial homology," as used herein refers to polynucleotides that are capable of hybridizing under moderately stringent conditions to a polynucleotide complementary to a sequence provided in SEQ ID NO:1 or SEQ ID NO:3, provided that the encoded SPL polypeptide variant retains SPL activity. Suitable moderately stringent conditions include prewashing in a
10 solution of 5X SSC, 0.5% SDS, 1.0 mM EDTA (pH 8.0); hybridizing at 50-65°C, 5X SSC, overnight; followed by washing twice at 65°C for 20 minutes with each of 2X, 0.5X and 0.2X SSC containing 0.1% SDS. Nucleotide sequences that, because of code degeneracy, encode a polypeptide encoded by any of the above sequences are also encompassed by the present invention.

15 Polypeptides of the present invention may be prepared by expression of recombinant DNA encoding the polypeptide in cultured host cells. Preferably, the host cells are bacteria, yeast, insect or mammalian cells, and more preferably the host cells are *S. cerevisiae bst1Δ* cells. The recombinant DNA may be cloned into any expression vector suitable for use within the host cell and
20 transfected into the host cell using techniques well known to those of ordinary skill in the art. A suitable expression vector contains a promoter sequence that is active in the host cell. A tissue-specific or conditionally active promoter may also be used. Preferred promoters express the polypeptide at high levels.

Optionally, the construct may contain an enhancer, a transcription
25 terminator, a poly(A) signal sequence, a bacterial or mammalian origin of replication and/or a selectable marker, all of which are well known in the art. Enhancer sequences may be included as part of the promoter region or separately. Transcription terminators are sequences that stop RNA polymerase-mediated transcription. The poly(A) signal may be contained within the termination
30 sequence or incorporated separately. A selectable marker includes any gene that confers a phenotype on the host cell that allows transformed cells to be identified.

Such markers may confer a growth advantage under specified conditions. Suitable selectable markers for bacteria are well known and include resistance genes for ampicillin, kanamycin and tetracycline. Suitable selectable markers for mammalian cells include hygromycin, neomycin, genes that complement a
5 deficiency in the host (*e.g.*, thymidine kinase and TK⁻cells) and others well known in the art. For yeast cells, one suitable selectable marker is URA3, which confers the ability to grow on medium without uracil.

DNA sequences expressed in this manner may encode a native SPL polypeptide (*e.g.*, human), or may encode portions or other variants of native SPL
10 polypeptide. DNA molecules encoding variants of a native SPL may generally be prepared using standard mutagenesis techniques, such as oligonucleotide-directed site-specific mutagenesis, and sections of the DNA sequence may be removed to permit preparation of truncated polypeptides.

To generate cells that express a polynucleotide encoding an SPL
15 polypeptide, cells may be transfected using any of a variety of techniques known in the art. Such transfection may result in stable transformants or may be transient. One suitable transfection technique is electroporation, which may be performed on a variety of cell types, including mammalian cells, yeast cells and bacteria, using commercially available equipment. Optimal conditions for
20 electroporation (including voltage, resistance and pulse length) are experimentally determined for the particular host cell type, and general guidelines for optimizing electroporation may be obtained from manufacturers. Other suitable methods for transfection will depend upon the type of cell used (*e.g.*, the lithium acetate method for yeast), and will be apparent to those of ordinary skill in the art.
25 Following transfection, cells may be maintained in conditions that promote expression of the polynucleotide within the cell. Appropriate conditions depend upon the expression system and cell type, and will be apparent to those skilled in the art.

SPL polypeptides may be expressed in transfected cells by
30 culturing the cell under conditions promoting expression of the transfected polynucleotide. Appropriate conditions will depend on the specific host cell and

expression vector employed, and will be readily apparent to those of ordinary skill in the art. For commercially available expression vectors, the polypeptide may generally be expressed according to the manufacturer's instructions. For certain purposes, expressed polypeptides of this invention may be isolated in substantially
5 pure form. Preferably, the polypeptides are isolated to a purity of at least 80% by weight, more preferably to a purity of at least 95% by weight, and most preferably to a purity of at least 99% by weight. In general, such purification may be achieved using, for example, the standard techniques of ammonium sulfate fractionation, SDS-PAGE electrophoresis, and/or affinity chromatography.

10 The present invention further provides antibodies that bind to an SPL polypeptide. Antibodies may function as modulating agents (as discussed further below) to inhibit or block SPL activity *in vivo*. Alternatively, or in addition, antibodies may be used within screens for endogenous SPL polypeptides or modulating agents, for purification of SPL polypeptides, for assaying the level
15 of SPL within a sample and/or for studies of SPL expression. Such antibodies may be polyclonal or monoclonal, and are generally specific for one or more SPL polypeptides and/or one or more variants thereof. Within certain preferred embodiments, antibodies are polyclonal.

Antibodies may be prepared by any of a variety of techniques
20 known to those of ordinary skill in the art (*see, e.g., Harlow and Lane, Antibodies: A Laboratory Manual*, Cold Spring Harbor Laboratory, 1988). In one such technique, an immunogen comprising an SPL polypeptide or antigenic portion thereof is initially injected into a suitable animal (*e.g., mice, rats, rabbits, sheep and goats*), preferably according to a predetermined schedule incorporating one or
25 more booster immunizations. The use of rabbits is preferred. To increase immunogenicity, an immunogen may be linked to, for example, glutaraldehyde or keyhole limpet hemocyanin (KLH). Following injection, the animals are bled periodically to obtain post-immune serum containing polyclonal anti-SPL antibodies. Polyclonal antibodies may then be purified from such antisera by, for
30 example, affinity chromatography using an SPL polypeptide or antigenic portion

thereof coupled to a suitable solid support. Such polyclonal antibodies may be used directly for screening purposes and for Western blots.

More specifically, an adult rabbit (e.g., NZW) may be immunized with 10 µg purified (e.g., using a nickel-column) SPL polypeptide emulsified in complete Freund's adjuvant (1:1 v/v) in a volume of 1mL. Immunization may be achieved via injection in at least six different subcutaneous sites. For subsequent immunizations, 5 µg of an SPL polypeptide may be emulsified in in complete Freund's adjuvant and injected in the same manner. Immunizations may continue until a suitable serum antibody titer is achieved (typically a total of about three immunizations). The rabbit may be bled immediately before immunization to obtain pre-immune serum, and then 7-10 days following each immunization.

For certain embodiments, monoclonal antibodies may be desired. Monoclonal antibodies may be prepared, for example, using the technique of Kohler and Milstein, *Eur. J. Immunol.* 6:511-519, 1976, and improvements thereto. Briefly, these methods involve the preparation of immortal cell lines capable of producing antibodies having the desired specificity (i.e., reactivity with the polypeptide of interest). Such cell lines may be produced, for example, from spleen cells obtained from an animal immunized as described above. The spleen cells are then immortalized by, for example, fusion with a myeloma cell fusion partner, preferably one that is syngeneic with the immunized animal. For example, the spleen cells and myeloma cells may be combined with a nonionic detergent for a few minutes and then plated at low density on a selective medium that supports the growth of hybrid cells, but not myeloma cells. A preferred selection technique uses HAT (hypoxanthine, aminopterin, thymidine) selection. After a sufficient time, usually about 1 to 2 weeks, colonies of hybrids are observed. Single colonies are selected and tested for binding activity against the polypeptide. Hybridomas having high reactivity and specificity are preferred.

Monoclonal antibodies may be isolated from the supernatants of growing hybridoma colonies. In addition, various techniques may be employed to enhance the yield, such as injection of the hybridoma cell line into the peritoneal cavity of a suitable vertebrate host, such as a mouse. Monoclonal antibodies may

then be harvested from the ascites fluid or the blood. Contaminants may be removed from the antibodies by conventional techniques, such as chromatography, gel filtration, precipitation, and extraction.

As noted above, the present invention provides agents that
5 modulate, preferably inhibit, the expression (transcription or translation), stability and/or activity of an SPL polypeptide. To identify such a modulating agent, any of a variety of screens may be performed. Candidate modulating agents may be obtained using well known techniques from a variety of sources, such as plants, fungi or libraries of chemicals, small molecules or random peptides. Antibodies
10 that bind to an SPL polypeptide, and anti-sense polynucleotides that hybridize to a polynucleotides that encodes an SPL, may be candidate modulating agents. Preferably, a modulating agent has a minimum of side effects and is non-toxic. For some applications, agents that can penetrate cells are preferred.

Screens for modulating agents that decrease SPL expression or
15 stability may be readily performed using well known techniques that detect the level of SPL protein or mRNA. Suitable assays include RNase protection assays, *in situ* hybridization, ELISAs, Northern blots and Western blots. Such assays may generally be performed using standard methods (*see* Sambrook et al., *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratories, Cold Spring
20 Harbor, NY, 1989). For example, to detect mRNA encoding SPL, a nucleic acid probe complementary to all or a portion of the SPL gene sequence may be employed in a Northern blot analysis of mRNA prepared from suitable cells. To detect SPL protein, a reagent that binds to the protein (typically an antibody, as described herein) may be employed within an ELISA or Western assay.
25 Following binding, a reporter group suitable for direct or indirect detection of the reagent is employed (*i.e.*, the reporter group may be covalently bound to the reagent or may be bound to a second molecule, such as Protein A, Protein G, immunoglobulin or lectin, which is itself capable of binding to the reagent). Suitable reporter groups include, but are not limited to, enzymes (*e.g.*, horseradish
30 peroxidase), substrates, cofactors, inhibitors, dyes, radionuclides, luminescent groups, fluorescent groups and biotin. Such reporter groups may be used to

directly or indirectly detect binding of the reagent to a sample component using standard methods known to those of ordinary skill in the art.

To use such assays for identifying a modulating agent, the level of SPL protein or mRNA may be evaluated in cells treated with one or more candidate modulating agents. An increase or decrease in SPL levels may be measured by evaluating the level of SPL mRNA and/or protein in the presence and absence of candidate modulating agent. For example, an antisense modulating agent may be evaluated by assaying the effect on SPL levels. Suitable cells for use in such assays include the breast cancer cell lines MCF-7 (ATCC Accession Number HTB-22) and MDA-MB-231 (ATCC Accession Number HTB-26). A candidate modulator may be tested by transfecting the cells with a polynucleotide encoding the candidate and evaluating the effect of expression of the polynucleotide on SPL levels. Alternatively, the cells may be contacted with a candidate modulator, typically in an amount ranging from about 10 nM to about 10 mM. A candidate that results in a statistically significant change in the level of SPL mRNA and/or protein is a modulating agent.

Alternatively, or in addition, a candidate modulating agent may be tested for the ability to inhibit SPL activity, using an *in vitro* assay as described herein (see Van Veldhoven and Mannaerts, *J. Biol. Chem.* 266:12502-07, 1991) that detects the degradation of labeled substrate (*i.e.*, sphingosine-1-phosphate, or a derivative thereof). Briefly, a solution (*e.g.*, a cellular extract) containing an SPL polypeptide (*e.g.*, 10 nM to about 10 mM) may be incubated with a candidate modulating agent (typically 1 nM to 10 mM, preferably 10 nM to 1 mM) and a substrate (*e.g.*, 40 μ M) at 37°C for 1 hour in the presence of, for example, 50 mM sucrose, 100 mM K-phosphate buffer pH 7.4, 25 mM NaF, 0.1% (w/v) Triton X-100, 0.5 mM EDTA, 2 mM DTT, 0.25 mM pyridoxal phosphate. Reactions may then be terminated and analyzed by thin-layer chromatography to detect the formation of labeled fatty aldehydes and further metabolites. A modulating agent (*e.g.*, an antibody) that inhibits SPL activity results in a statistically significant decrease in the degradation of sphingosine-1-phosphate, relative to the level of

degradation in the absence of modulating agent. Such modulating agents may be used to inhibit SPL activity in a cell culture or a mammal, as described below.

A modulating agent may additionally comprise, or may be associated with, a targeting component that serves to direct the agent to a desired tissue or cell type. As used herein, a "targeting component" may be any substance (such as a compound or cell) that, when linked to a compound enhances the transport of the compound to a target tissue, thereby increasing the local concentration of the compound. Targeting components include antibodies or fragments thereof, receptors, ligands and other molecules that bind to cells of, or in the vicinity of, the target tissue. Known targeting components include hormones, antibodies against cell surface antigens, lectins, adhesion molecules, tumor cell surface binding ligands, steroids, cholesterol, lymphokines, fibrinolytic enzymes and other drugs and proteins that bind to a desired target site. In particular, anti-tumor antibodies and compounds that bind to an estrogen receptor may serve as targeting components. An antibody employed in the present invention may be an intact (whole) molecule, a fragment thereof, or a functional equivalent thereof. Examples of antibody fragments are F(ab')₂, -Fab', Fab and F[v] fragments, which may be produced by conventional methods or by genetic or protein engineering. Linkage may be via any suitable covalent bond using standard techniques that are well known in the art. Such linkage is generally covalent and may be achieved by, for example, direct condensation or other reactions, or by way of bi- or multi-functional linkers.

For *in vivo* use, a modulating agent as described herein is generally incorporated into a pharmaceutical composition prior to administration. A pharmaceutical composition comprises one or more modulating agents in combination with a physiologically acceptable carrier. To prepare a pharmaceutical composition, an effective amount of one or more modulating agents is mixed with any pharmaceutical carrier(s) known to those skilled in the art to be suitable for the particular mode of administration. A pharmaceutical carrier may be liquid, semi-liquid or solid. Solutions or suspensions used for parenteral, intradermal, subcutaneous or topical application may include, for

example, a sterile diluent (such as water), saline solution, fixed oil, polyethylene glycol, glycerine, propylene glycol or other synthetic solvent; antimicrobial agents (such as benzyl alcohol and methyl parabens); antioxidants (such as ascorbic acid and sodium bisulfite) and chelating agents (such as ethylenediaminetetraacetic acid (EDTA)); buffers (such as acetates, citrates and phosphates). If administered intravenously, suitable carriers include physiological saline or phosphate buffered saline (PBS), and solutions containing thickening and solubilizing agents, such as glucose, polyethylene glycol, polypropylene glycol and mixtures thereof. In addition, other pharmaceutically active ingredients (including other anti-cancer agents) and/or suitable excipients such as salts, buffers and stabilizers may, but need not, be present within the composition.

A modulating agent may be prepared with carriers that protect it against rapid elimination from the body, such as time release formulations or coatings. Such carriers include controlled release formulations, such as, but not limited to, implants and microencapsulated delivery systems, and biodegradable, biocompatible polymers, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, polyorthoesters, polylactic acid and others known to those of ordinary skill in the art.

Administration may be achieved by a variety of different routes, including oral, parenteral, nasal, intravenous, intradermal, subcutaneous or topical. Preferred modes of administration depend upon the nature of the condition to be treated or prevented. An amount that, following administration, inhibits, prevents or delays the progression and/or metastasis of a cancer is considered effective. Preferably, the amount administered is sufficient to result in regression, as indicated by 50% mass or by scan dimensions. The precise dosage and duration of treatment is a function of the disease being treated and may be determined empirically using known testing protocols or by testing the compositions in model systems known in the art and extrapolating therefrom. Controlled clinical trials may also be performed. Dosages may also vary with the severity of the condition to be alleviated. A pharmaceutical composition is generally formulated and administered to exert a therapeutically useful effect

while minimizing undesirable side effects. The composition may be administered one time, or may be divided into a number of smaller doses to be administered at intervals of time. For any particular subject, specific dosage regimens may be adjusted over time according to the individual need.

5 As an alternative to direct administration of a modulating agent, a polynucleotide encoding a modulating agent may be administered. Such a polynucleotide may be present in a pharmaceutical composition within any of a variety of delivery systems known to those of ordinary skill in the art, including nucleic acid, bacterial and viral expression systems, and colloidal dispersion
10 systems such as liposomes. Appropriate nucleic acid expression systems contain the necessary DNA sequences for expression in the patient (such as a suitable promoter and terminating signal, as described above). The DNA may also be "naked," as described, for example, in Ulmer et al., *Science* 259:1745-49, 1993.

 Various viral vectors that can be used to introduce a nucleic acid
15 sequence into the targeted patient's cells include, but are not limited to, vaccinia or other pox virus, herpes virus, retrovirus, or adenovirus. Techniques for incorporating DNA into such vectors are well known to those of ordinary skill in the art. Another delivery system for polynucleotides is a colloidal dispersion system. Colloidal dispersion systems include macromolecule complexes,
20 nanocapsules, microspheres, beads, and lipid-based systems including oil-in-water emulsions, micelles, mixed micelles, and liposomes. The preparation and use of liposomes is well known to those of ordinary skill in the art.

 Within certain aspects of the present invention, one or more modulating agents may be used to modulate SPL expression and/or activity *in vitro*, in a cell or in a mammal. *In vitro*, an SPL polypeptide may be contacted
25 with a modulating agent that inhibits SPL activity (e.g., certain antibodies). For use within a cell or a mammal, such modulation may be achieved by contacting a target cell with an effective amount of a modulating agent, as described herein. Administration to a mammal may generally be achieved as described above.

30 As noted above, inhibition of SPL expression and/or activity provides a method for inhibiting the growth (*i.e.*, proliferation) of a cancer cell,

either in culture or in a mammal afflicted with cancer. *In vivo*, such inhibition may also be used to inhibit cancer development, progression and/or metastasis. Accordingly, one or more modulating agents as provided herein may be administered as described above to a mammal in need of anti-cancer therapy.

- 5 Patients that may benefit from administration of a modulating agent are those afflicted with cancer. Such patients may be identified based on standard criteria that are well known in the art. Within preferred embodiments, a patient is afflicted with breast cancer, as identified based on tissue biopsy and microscopic evaluation, using techniques well known in the art. In particular, patients whose
10 tumor cells contain a tissue-specific deletion and/or alteration within an endogenous SPL gene may benefit from administration of a modulating agent, as provided herein.

Within other aspects, the present invention provides methods and kits for diagnosing cancer and/or identifying individuals with a risk for metastasis
15 that is higher or lower than average. It has been found, within the context of the present invention, that certain human tumor cells contain an altered SPL gene. In particular, certain brain tumor cells contain a deletion of residues 354 to 433 of the human SPL sequence indicated in Figure 8 and SEQ ID NO:4. Specific alterations present in other tumor cells, such as breast tumor cells, may be readily
20 identified using standard techniques, such as PCR. Alterations that may be associated with a particular tumor include amino acid deletions, insertions, substitutions and combinations thereof. Methods in which the presence or absence of such an alteration is determined may generally be used to detect cancer and to evaluate the prognosis for a patient known to be afflicted with cancer.

25 To detect an altered SPL gene, any of a variety of well-known techniques may be used including, but not limited to, PCR and hybridization techniques. Any sample that may contain cancerous cells may be assayed. In general, suitable samples are tumor biopsies. Within a preferred embodiment, a sample is a breast tumor biopsy.

30 Kits for diagnosing or evaluating the prognosis of a cancer generally comprise reagents for use in the particular assay to be employed. In

general, a kit of the present invention comprises one or more containers enclosing elements, such as probes, reagents or buffers, to be used in an assay. For example, a kit may contain one or more polynucleotide probes comprising at least 100 nucleotides, and preferably at least 200 nucleotides, complementary to an SPL mRNA. Such probe(s) may be used to detect an altered SPL gene by hybridization. For example, a kit may contain one probe that hybridizes to a region of an SPL gene that is not generally altered in tumors (a control) and a second probe that hybridizes to a region commonly deleted in breast cancer. A sample that contains mRNA that hybridizes to the first probe, and not to the second (using standard techniques) contains an altered SPL gene. Suitable control probes include probes that hybridize to a portion of the SPL gene outside of the commonly deleted region encoding amino acid residues 354 to 433; suitable probes for an altered region include probes that hybridize to a portion of the SPL gene that encodes amino acid residues 354 to 433. Alternatively, a kit may comprise one or more primers for PCR analyses, which may be readily designed based upon the sequences provided herein by those of ordinary skill in the art. Optionally, a kit may further comprise one or more solutions, compounds or detection reagents for use within an assay as described above.

In a related aspect of the present invention, kits for detecting SPL are provided. Such kits may be designed for detecting the level of SPL or nucleic acid encoding SPL within a sample, or may detect the level of SPL activity as described herein. A kit for detecting the level of SPL, or nucleic acid encoding SPL, typically contains a reagent that binds to the SPL protein, DNA or RNA. To detect nucleic acid encoding SPL, the reagent may be a nucleic acid probe or a PCR primer. To detect SPL protein, the reagent is typically an antibody. The kit may also contain a reporter group suitable for direct or indirect detection of the reagent as described above.

Within further aspects, the present invention provides transgenic mammals in which SPL activity is reduced, compared to a wild-type animal. Such animals may contain an alteration, insertion or deletion in an endogenous SPL gene, or may contain DNA encoding a modulating agent that inhibits

expression or activity of an SPL gene. Transgenic animals may be generated using techniques that are known to those of ordinary skill in the art. For example, a transgenic animal containing an insertion or deletion in the coding region for the SPL gene may be generated from embryonic stem cells, using standard techniques. Such stem cells may be generated by first identifying the full genomic sequence of the gene encoding the SPL, and then creating an insertion or deletion in the coding region in embryonic stem cells. Alternatively, appropriate genetically altered embryonic stem cells may be identified from a bank. Using the altered stem cells, hybrid animals may be generated with one normal SPL gene and one marked, abnormal gene. These hybrids may be mated, and homozygous progeny identified.

Transgenic animals may be used for a variety of purposes, which will be apparent to those of ordinary skill in the art. For example, such animals may be used to prepare cell lines from different tissues, using well known techniques. Such cell lines may be used, for example, to evaluate the effect of the alteration, and to test various candidate modulators.

Summary of Sequence Listing

SEQ ID NO:1 is cDNA sequence encoding mouse endogenous SPL.

SEQ ID NO:2 is amino acid sequence of mouse endogenous SPL.

SEQ ID NO:3 is cDNA sequence encoding human endogenous SPL.

SEQ ID NO:4 is amino acid sequence of human endogenous SPL.

SEQ ID NO:5 is cDNA sequence encoding *C. elegans* endogenous SPL.

SEQ ID NO:6 is amino acid sequence of *C. elegans* endogenous SPL.

SEQ ID NO:7 is cDNA sequence encoding yeast endogenous SPL.

SEQ ID NO:8 is amino acid sequence of yeast endogenous SPL.

SEQ ID NO:9 is cDNA sequence encoding an altered human SPL.

SEQ ID NO:10 is amino acid sequence of an altered human SPL.

The following Examples are offered by way of illustration and not
by way of limitation.

5

EXAMPLES

Example 1Isolation and Characterization of SPL cDNA from Yeast

5 This Example illustrates the preparation of an *S. cerevisiae* cDNA molecule encoding an endogenous SPL polypeptide.

Wild-type yeast cells (SGP3 (Garrett and Broach, *Genes and Dev.* 3:1336-1348, 1989); *leu2-3,112 trp1 ura3-52 his3 ade8 ras1::HIS3*) were transformed with a yeast genomic library carried on the pRS202 high-copy shuttle
10 vector (Sikorski and Heiter, *Genetics* 122:19-27, 1989) containing a selectable nutritional marker (*URA3*). pRS202 is a modified version of the pRS306 vector, into which a 2 micron plasmid piece was inserted. Inserts from this library are approximately 6-8 kb in length. Wild type yeast were transformed with the high copy library as described by Ito et al., *J. Bact.* 153:163-68, 1983, selected for
15 uracil prototrophy (*i.e.*, the ability to grow on medium lacking uracil), and transformants were pooled and replated at a concentration of 10^6 cells per plate onto 1 mM D-erythro-sphingosine plates.

Six transformants which grew large colonies on 1mM D-erythro-sphingosine plates were grown in selective medium, and control SGP3 colonies
20 were grown in minimal medium, at 30°C until saturated. Absorbance at 660 nm was used to correct for small variations in cell concentration between cultures. Serial dilutions were performed, and cells were template-inoculated onto 1 mM D-erythro-sphingosine plates and incubated at 30°C for 48 hours.

The most highly represented insert, 13-1, was subcloned and
25 sequenced, and named *BST1* (bestower of sphingosine tolerance; GenBank accession number U51031; *Saccharomyces cerevisiae* genome database accession number YDR294C). The *BST1* nucleotide sequence encodes a previously unknown predicted protein of 65,523 kilodaltons and 589 amino acids in length. This sequence is 23% identical to *gadA* and *gadB*, two nearly identical *E. coli*
30 genes encoding glutamate decarboxylase (GAD), a pyridoxal-5'-phosphate-dependent enzyme which catalyzes synthesis of the neurotransmitter γ -amino

butyric acid. *BST1* has been localized to *S. cerevisiae* chromosome 4. The sequence of *BST1* is provided in Figure 1 and SEQ ID NO:7.

To explore the function of *BST1*, a deletion strain was created through homologous recombination using a *NEO* selectable marker (Wach et al.,
5 *Yeast* 10:1793-1808, 1994). Genomic *BST1* was replaced with *kanMX* (Wach et al., *Yeast* 10:1793-1808, 1994), which confers resistance to G418. Disruption was confirmed using PCR amplification of genomic DNA from G418 resistant clones, using primers to genomic sequence just 5' and 3' to the region replaced by the disruption. Deletion of *BST1* and all subsequent biological studies were
10 performed in both SGP3 and in JK93d (Hietman et al., *Proc. Natl. Acad. Sci. USA* 88:1948-52, 1991); *ura3-52 leu2-3,112 his4 trp1 rme1*). Heterozygous diploids were sporulated, and spores segregated 2:2 for G418 resistance. Both G418 resistant and sensitive progeny were viable, indicating that *BST1* is not an essential gene.

15 Analysis of GAD activity in cytosolic extracts from wild type, *BST1* overexpression and *bst1Δ* strains indicated that *BST1* does not encode the *S. cerevisiae* homologue of GAD. However, deletion of *BST1* was associated with severe sensitivity to D-erythro-sphingosine. Concentrations as low as 10 μM sphingosine completely inhibited growth of *bst1Δ* strains but had no effect on the
20 viability of wild type cells. In comparison to the control strain, the *bst1Δ* strain also demonstrated greater sensitivity to 100 μM phytosphingosine, the long chain base endogenous to *S. cerevisia*. No difference between the growth of wild type and *BST1* overexpression strains on phytosphingosine, which is only minimally toxic to wild type cells at this concentration, was observed.

25 To determine whether differences in sphingosine uptake or metabolism were responsible for these sensitivity differences, *BST1* wild type, overexpression and *bst1Δ* strains were exposed to [C3-³H]labeled sphingosine (American Radiolabeled Chemical, Inc., St. Louis, MO), washed in sterile water and subjected to Bligh-Dyer extractions (Bligh and Dyer, *Can. J. Buichem.*
30 *Physiol.* 37:911-17, 1959). There were no major differences in sphingosine

recovery among the three strains. However, the aqueous phase from the *bst1* Δ strain contained a ten-fold increase in radioactivity over that of control and *BST1* overexpression strains. Thin layer chromatography (TLC) analysis of the lipid fractions in butanol:acetic acid:water (3:1:1) revealed a sphingosine band which
5 appeared equivalent in each strain.

Radioactive sphingosine-1-phosphate (S-1-P) was also observed in the extracts from the *bst1* Δ strain, but not in the wild type or *BST1* overexpression strains. This compound accumulated rapidly, reaching a plateau by 60 minutes. Three separate TLC conditions were used to confirm the presence of S-1-P.
10 These conditions, along with the resulting RF values, are shown below:

	butanol:water:acetic acid (3:1:1)
	.47
	chloroform:methanol:water (60:35:8)
15	.22
	chloroform:methanol:water:acetic acid (30:30:2:5)
	.33

Hyperaccumulation of S-1-P and hypersensitivity to *D-erythro*-
20 sphingosine suggest a failure to metabolize S-1-P, indicating that *BST1* is a yeast SPL. To confirm this identification, lyase activity in *BST1* wild type, overexpression and deletion strains were evaluated as described by Veldhoven and Mannaerts, *J. Biol. Chem.* 266:12502-07, 1991, using unlabeled *D-erythro*-dihydrosphingosine-1-phosphate (Biomol, Plymouth Meeting, PA) and *D-erythro*-
25 dihydrosphingosine [4,5-³H]1-phosphate (American Radiolabeled Chemicals, Inc., St. Louis, MO). Specific activity was 100 mCi/mmol. SPL activity was found to correlate with *BST1* expression, confirming *BST1* to be the yeast homologue of sphingosine-1-phosphate lyase.

These results indicate that *BST1* is a yeast SPL, and that SPL catalyzes a rate-limiting step in sphingolipid catabolism. Regulation of SPL activity may therefore result in regulation of intracellular S-1-P levels.

5

Example 2

Isolation and Characterization of SPL cDNA from *C. elegans* and Mouse

This Example illustrates the identification of endogenous SPL cDNAs from *C. elegans* and *Mus musculus*.

10 Comparison of the yeast *BST1* sequence to sequences within the GenBank database identified a full length gene from *C. elegans* that was identified during the systematic sequencing of the *C. elegans* genome. This sequence was found to encode SPL, and is shown in Figure 2 and SEQ ID NOs:5 and 6. This and other DNA homology searches described herein were performed
15 via the National Center for Biotechnology Information website using BLAST search program.

Using both *S. cerevisiae* and *C. elegans* SPL sequences to search the EST database, an expressed sequence tag from early embryonic cells of the mouse (day 8 embryo, strain C57BL/6J) was identified. The cDNA clone
20 containing this putative mouse SPL was purchased from Genome Systems, Inc (St. Louis, MO). Completion of the full length cDNA sequence revealed an 1709 bp open reading frame (Figure 3 and SEQ ID NOs:1 and 2). This mouse sequence showed significant homology to *BST1* and to other pyridoxal phosphate-binding enzymes such as glutamate decarboxylase, with greatest conservation surrounding
25 the predicted pyridoxal phosphate-binding lysine (Figure 4). Since the two genes encoding mouse glutamate decarboxylase have been identified previously, and the identified sequence was unique and had no known function, it was a likely candidate mouse SPL gene.

To confirm the SPL activity of the mouse gene, a two step process
30 was undertaken. First, the sequence was cloned into the high-copy yeast expression vector, pYES2 (Invitrogen, Inc., Carlsbad, CA), in which the gene of

interest is placed under control of the yeast GAL promoter and is, therefore, transcriptionally activated by galactose and repressed by glucose. pYES2 also contains the *URA3* gene (which provides transformants the ability to grow in media without uracil) and an ampicillin resistance marker and origin of replication
5 functional in *E. coli*.

The expression vector containing the full-length mouse SPL gene was then introduced into the yeast *bst1Δ* strain which, as noted above, is extremely sensitive to D-erythro-sphingosine, as a result of metabolism of sphingosine to S-1-P. S-1-P cannot be further degraded in the absence of SPL
10 activity and overaccumulates, causing growth inhibition. Transformation was performed using the lithium acetate method (Ito et al., *J. Bact.* 153:163-68, 1983). Transformants were grown on medium containing 20g/L galactose and selected for uracil prototrophy.

Transformants were then evaluated for sphingosine resistance.
15 Strains of interest were grown to saturation in liquid culture for 2-3 days. They were then resuspended in minimal medium, placed in the first row of a 96-well plate and diluted serially from 1:2 to 1:4000 across the plate. The cultures were then template inoculated onto a control plate (YPD) and a plate containing minimal synthetic media supplemented with 50 μM D-erythro-sphingosine
20 (Sigma Chemical Co., St. Louis, MO) and 0.0015% NP40 (Sigma Chemical Co.). At this concentration of NP40, no effects on cell viability were observed. Plates were incubated at 30°C for two days and assessed visually for differences in growth. Transformants containing the mouse SPL gene were resistant to sphingosine present in galactose-containing plates (Figure 5). A strain
25 transformed with vector alone remained sensitive to sphingosine. Therefore, the mouse SPL gene was capable of reversing the sphingosine-sensitive phenotype of a yeast *bst1Δ* strain.

In order to determine whether the mouse SPL gene was able to restore biochemical SPL activity to the *bst1Δ* strain, the untransformed *bst1Δ*
30 strain, and the *bst1Δ* strain transformed with pYES2 containing either *BST1* or the

putative mouse SPL gene were grown to exponential phase ($A_{600}=1.0$) in either minimal (JS16) or uracil medium containing galactose as a carbon source. Whole cell extracts were prepared from each strain as described above, adjusted for protein concentration, and evaluated for sphingosine phosphate lyase activity as described above, using ^3H -dihydrosphingosine-1-phosphate (American Radiolabeled Chemicals, Inc., St. Louis, MO). Qualitative analysis of product was performed by autoradiography. Quantitative measurement was performed by scraping TLC plates and determining radioactivity present using a standard scintillation counter.

10 The results of the sphingosine phosphate lyase assays are shown in Figures 6A and 6B. Expression of both the yeast and mouse sequences restored SPL activity to the *bst1* Δ strain, whereas vector alone had no effect, confirming the identity of the mouse sequence as SPL.

To determine whether the expression of the mouse SPL transcript
15 coincided with previously reported tissue-specific SPL activity in the mouse, total RNA was obtained from a variety of mouse tissues and probed with the complete mouse SPL cDNA sequence. Northern analysis was performed as described by Thomas, *Proc. Natl. Acad. Sci. USA* 77:5201, 1980, using a full length mouse SPL cDNA probe labeled by random labeling technique (Cobianchi and Wilson,
20 *Meth. Enzymol.* 152:94-110, 1987). This analysis revealed a pattern of expression consistent with the known SPL activity in various mouse tissues, providing further confirmation that this sequence encodes mouse SPL (Figure 7).

Example 3

25 Isolation and Characterization of Human SPL cDNA

This Example illustrates the identification of an endogenous human cDNA.

An EST database was searched using the mouse SPL sequence described herein. Two distinct EST sequences having strong homology to the
30 mouse sequence were identified from human sources. One of these sequences corresponded to the C-terminus, and the other corresponded to the N-terminus.

Primers were designed based on these sequences, and a DNA fragment was amplified by PCR from a human expression library made from human glioblastoma multiforme tissue RNA. The fragment was sequenced and was shown to contain a deletion, so the primers were used to amplify the gene from
5 human fibroblast RNA. This gene has the sequence provided in SEQ ID NO:3, and the sequence of the gene containing the deletion is provided in SEQ ID NO:9.

From the foregoing, it will be appreciated that, although specific embodiments of the invention have been described herein for the purpose of
10 illustration, various modifications may be made without deviating from the spirit and scope of the invention.

Claims

1. An isolated polynucleotide comprising a sequence selected from the group consisting of:
 - (a) a sequence recited in SEQ ID NO:1;
 - (b) a sequence recited in SEQ ID NO:3;
 - (c) nucleotide sequences that hybridize to a polynucleotide complementary to either of the foregoing sequences under moderately stringent conditions, wherein the nucleotide sequences encode polypeptides having sphingosine-1-phosphate lyase activity; and
 - (d) nucleotide sequences that encode a polypeptide encoded by any of the foregoing sequences.
2. An isolated polynucleotide encoding a polypeptide recited in SEQ ID NO:2, or a variant of such a polypeptide that has sphingosine-1-phosphate lyase activity.
3. An isolated polynucleotide encoding a polypeptide comprising a sequence recited in SEQ ID NO:4, or a variant of such a polypeptide that has sphingosine-1-phosphate lyase activity.
4. A recombinant expression vector comprising a polynucleotide according to any one of claims 1-3.
5. A host cell transformed or transfected with an expression vector according to claim 4.
6. An isolated polynucleotide comprising at least 100 nucleotides complementary to a sequence recited in SEQ ID NO:1 or 3.

7. A method for preparing a sphingosine-1-phosphate lyase, the method comprising culturing a host cell transformed or transfected with a polynucleotide according to any one of claims 1-3 under conditions promoting expression of the polynucleotide and recovering a sphingosine-1-phosphate lyase.

8. A polypeptide comprising an amino acid sequence encoded by a polynucleotide according to claim 1.

9. A polypeptide comprising an amino acid sequence recited in SEQ ID NO:2 or 4, or a variant thereof, wherein the polypeptide has sphingosine-1-phosphate lyase activity.

10. A method for identifying an agent that modulates sphingosine-1-phosphate lyase activity, comprising:

(a) contacting a candidate agent with cells that express sphingosine-1-phosphate lyase; and

(b) subsequently measuring the level of sphingosine-1-phosphate lyase or mRNA encoding sphingosine-1-phosphate lyase in the cells, relative to a predetermined level in the absence of candidate agent, and therefrom identifying an agent that modulates sphingosine-1-phosphate lyase activity.

11. A method for identifying an agent that modulates sphingosine-1-phosphate lyase activity, comprising:

(a) contacting a candidate agent with a polypeptide comprising a sequence recited in any one of SEQ ID NOs: 2, 4, 6 or 8, or a variant of such a sequence having sphingosine-1-phosphate lyase activity, wherein the step of contacting is carried out under conditions and for a time sufficient to allow the candidate modulator to interact with the polypeptide; and

(b) subsequently measuring the ability of the polypeptide to degrade sphingosine-1-phosphate or a derivative thereof, relative to an ability in the absence

of candidate agent, and therefrom identifying an agent that modulates sphingosine-1-phosphate lyase activity.

12. A method according to claim 11, wherein the step of contacting is performed by incubating a cell expressing the polypeptide with the candidate modulator, and wherein the step of measuring the ability to degrade sphingosine-1-phosphate is performed using an *in vitro* assay and a cellular extract.

13. A pharmaceutical composition comprising an agent that modulates sphingosine-1-phosphate lyase activity in combination with a pharmaceutically acceptable carrier.

14. A composition according to claim 13, wherein the sphingosine-1-phosphate lyase comprises a sequence recited in any one of SEQ ID NOs:2, 4 or 6.

15. A composition according to claim 13, wherein the agent inhibits expression of an endogenous sphingosine-1-phosphate lyase gene.

16. A composition according to claim 15, wherein the agent comprises a polynucleotide.

17. A composition according to claim 13, wherein the agent inhibits the ability of an endogenous sphingosine-1-phosphate lyase to degrade sphingosine-1-phosphate.

18. A composition according to claim 17, wherein the agent comprises an antibody or an antigen-binding fragment thereof.

19. A method for modulating sphingosine-1-phosphate lyase activity, comprising contacting a sphingosine-1-phosphate lyase with an effective amount of an agent that modulates sphingosine-1-phosphate lyase activity, wherein the step of contacting is

performed under conditions and for a time sufficient to allow the agent and the sphingosine-1-phosphate lyase to interact.

20. A method according to claim 19, wherein the step of contacting is performed by incubating a cell expressing the polypeptide with the agent.

21. A method according to claim 19, wherein the agent inhibits expression of an endogenous sphingosine-1-phosphate lyase gene.

22. A method according to claim 21, wherein the agent comprises a polynucleotide.

23. A method according to claim 19, wherein the agent is capable of inhibiting the ability of a polypeptide comprising a sequence recited in any one of SEQ ID NOs: 2, 4 or 6 to degrade sphingosine-1-phosphate.

24. A method for inhibiting the growth of a cancer cell, comprising contacting a cancer cell with an agent that inhibits sphingosine-1-phosphate lyase activity.

25. A method according to claim 24, wherein the agent inhibits expression of an endogenous sphingosine-1-phosphate lyase gene.

26. A method according to claim 25, wherein the agent comprises a polynucleotide according to claim 6.

27. A method according to claim 24, wherein the agent is capable of inhibiting the ability of a polypeptide comprising a sequence recited in any one of SEQ ID NOs: 2, 4 or 6 to degrade sphingosine-1-phosphate.

28. A method according to claim 24, wherein the cancer cell is a breast cancer cell.

29. A method for inhibiting the development and/or metastasis of a cancer in a mammal, comprising administering to a mammal an agent that inhibits sphingosine-1-phosphate lyase activity.

30. A method according to claim 29, wherein the agent inhibits expression of an endogenous sphingosine-1-phosphate lyase gene.

31. A method according to claim 30, wherein the agent comprises a polynucleotide according to claim 6.

32. A method according to claim 29, wherein the agent is capable of inhibiting the ability of a polypeptide comprising a sequence recited in any one of SEQ ID NOs: 2, 4 or 6 to degrade sphingosine-1-phosphate.

33. A method according to claim 29, wherein the agent is linked to a targeting component.

34. A method according to claim 33, wherein the targeting component is an anti-tumor antibody.

35. A method according to claim 33, wherein the targeting component binds to an estrogen receptor.

36. A method according to claim 29, wherein the mammal is afflicted with breast cancer.

37. A method for diagnosing a cancer in a mammal, comprising detecting an alteration in an endogenous sphingosine-1-phosphate lyase gene in a sample obtained from a mammal, and therefrom diagnosing a cancer in the mammal.

38. A method according to claim 37, wherein the alteration is a deletion.
39. A method according to claim 37, wherein the cancer is breast cancer and the sample is a breast tumor biopsy.
40. A method for evaluating a cancer prognosis, comprising determining the presence or absence of an alteration in an endogenous sphingosine-1-phosphate lyase gene in a sample obtained from a mammal afflicted with cancer, and therefrom determining a prognosis.
41. A method according to claim 40, wherein the alteration is a deletion.
42. A method according to claim 41, wherein the deletion comprises amino acid residues 354-433 of SEQ ID NO:4.
43. A method according to claim 40, wherein the cancer is breast cancer and the sample is a breast tumor biopsy.
44. An isolated antibody that binds to a polypeptide having a sequence recited in any one of SEQ ID NOs: 2, 4 or 6.
45. A monoclonal antibody that binds to a polypeptide having a sequence recited in any one of SEQ ID NOs: 2, 4 or 6.
46. An antibody according to claim 44 or claim 45, wherein the antibody inhibits the ability of a polypeptide having a sequence recited in any one of SEQ ID NOs: 2, 4 or 6 to degrade sphingosine-1-phosphate.
47. A method for detecting sphingosine-1-phosphate lyase in a sample, comprising:

(a) contacting a sample with an antibody according to claim 44 or claim 45 under conditions and for a time sufficient to allow the antibody to bind to sphingosine-1-phosphate lyase; and

(b) detecting in the sample the presence of sphingosine-1-phosphate lyase bound to the antibody.

48. A kit for detecting sphingosine-1-phosphate lyase in a sample, comprising an antibody according to claim 44 or claim 45 and a buffer or detection reagent.

49. A kit for detecting an alteration in a sphingosine-1-phosphate gene in a sample, comprising a polynucleotide according to claim 6 and a detection reagent.

50. A transgenic animal in which sphingosine-1-phosphate lyase activity is reduced compared to a wild-type animal.

51. A cell line derived from a transgenic animal according to claim 50.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

(i) APPLICANT: Saba, Julie D.
Zhou, Jianhui

(ii) TITLE OF INVENTION: SPHINGOSINE-1-PHOSPHATE LYASE
POLYPEPTIDES, POLYNUCLEOTIDES AND MODULATING AGENTS AND
METHODS OF USE THEREFOR

(iii) NUMBER OF SEQUENCES: 10

(iv) CORRESPONDENCE ADDRESS:

(A) ADDRESSEE: SEED and BERRY LLP
(B) STREET: 6300 Columbia Center, 701 Fifth Avenue
(C) CITY: Seattle
(D) STATE: Washington
(E) COUNTRY: USA
(F) ZIP: 98104

(v) COMPUTER READABLE FORM:

(A) MEDIUM TYPE: Floppy disk
(B) COMPUTER: IBM PC compatible
(C) OPERATING SYSTEM: PC-DOS/MS-DOS
(D) SOFTWARE: PatentIn Release #1.0, Version #1.30

(vi) CURRENT APPLICATION DATA:

(A) APPLICATION NUMBER: US
(B) FILING DATE: 29-SEP-1997
(C) CLASSIFICATION:

(viii) ATTORNEY/AGENT INFORMATION:

(A) NAME: David, Maki J.
(B) REGISTRATION NUMBER: 31,392
(C) REFERENCE/DOCKET NUMBER: 200116.402

(ix) TELECOMMUNICATION INFORMATION:

(A) TELEPHONE: (206) 622-4900

(B) TELEFAX: (206) 682-6031

(2) INFORMATION FOR SEQ ID NO:1:

(i) SEQUENCE CHARACTERISTICS:

(A) LENGTH: 1707 base pairs

(B) TYPE: nucleic acid

(C) STRANDEDNESS: single

(D) TOPOLOGY: linear

(ix) FEATURE:

(A) NAME/KEY: CDS

(B) LOCATION: 1..1704

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:1:
